# System-level Functional Programming with Linear Types

Sebastian Selander and Samuel Hammersberg

### System level programming today

In todays world we are blessed with a lot of choices for system level programming:

- C
- C++
- Rust
- And more . . .

### System level programming today

Although these languages are great, they are missing some things that some developers enjoy:

- Referential transparency
- Purity
- Strongly typed

# Functional programming to the rescue!

What does FP not lack in?

- Referential transparency
- Purity
- Strongly typed

You could of course create a FP language without these

#### Functional programming to the rescue!

But does not functional programming require some sort of garbage collector?

**No!** We can use linear types!

Every variable must be used **exactly once** 

```
• Linear arrow: —○
• Normal arrow: →

append :: [a] -o [a] -o [a]
append [] ys = ys
append (x:xs) ys = x : append xs ys -- good

const :: a -o b -o c
const a b = a -- error
```

Now append can mutate ys in a safe manner

For a function f with arguments x using **exactly once** means:

- Returning x unmodified.
  - + f x = x

For a function f with arguments x using **exactly once** means:

- Returning x unmodified.
  - + f x = x
- Passing x to a linear function g and using the result exactly once in the same fashion.
  - + f x = g x

For a function f with arguments x using **exactly once** means:

• Returning x unmodified.

```
+ f x = x
```

• Passing x to a linear function g and using the result exactly once in the same fashion.

```
\rightarrow f x = g x
```

• Pattern-matching on x and using each argument exactly once in the same fashion.

```
▶ f x = case x of
Pair a b -> a + b
```

For a function f with arguments x using **exactly once** means:

• Returning x unmodified.

```
+ f x = x
```

• Passing x to a linear function g and using the result exactly once in the same fashion.

```
+ f x = g x
```

• Pattern-matching on x and using each argument exactly once in the same fashion.

```
▶ f x = case x of
Pair a b -> a + b
```

 Calling it as a function and using the result exactly once in the same fashion.

```
f x = x + 1
q = let k = f 0 in f k
```

### System-level Functional Language (SLFL)

The point of our thesis will be to create a compiler for a SLFL

While the language is a system-level language, we want to add several higher level concepts such as:

- Closures
  - Allows lambads to capture variables from their environment

```
fun :: Int -> (Int -> Int)
fun x = y -> x + y -- x is captured here
```

- Records
  - Data types with named fields. Pretty simple
- Recursive & Contiguous Data Types
  - Trees, linked lists etc and Vectors/Arrays
- Laziness

#### How will the language be evaluated?

Objectively evaluating languages is hard, but some things can be done!

#### • Performance:

Simple programs will be written in another system-level language (C etc) and SLFL

Programs will be compared based on execution time and memory usage

#### · Binary size:

A system-level language should ideally produce small binaries for portability

Our thesis will not focus a lot on this, but it is an interesting metric nonetheless

# Why us?

#### Why us?

Both of us have a lot of experience when it comes to language development *and* functional programming.

- All FP courses
- All language development courses
- Made a functional programming language for our bachelor thesis
- Motivated

# Risk assessment and proposed mitigation

- Too complex
- Lack prerequisite knowledge
