Towards a System-Level Functional Language

Sebastian Selander and Samuel Hammersberg

System level programming today

In todays world we are blessed with a lot of choices for system level programming:

- C
- C++
- Rust
- And more . . .

System level programming today

Although these languages are great, they are missing some things that some developers enjoy:

- Referential transparency
- Purity
- Strongly typed

What does FP not lack in?

- Referential transparency
- Purity
- · Strongly typed

You could of course create a FP language without these

Is system-level programming we often have to care about memory, but most functional languages use garbage collectors!

Most of the time a lot of copying is done when updating values, and the old value has to be garbage collected

```
update :: Int -> [Int] -> [Int]
update a (x:y:z:as) = [x, y, a] : as
```

A garbage collector is not preferred for system-level programming as we want control over memory!

So are we stuck with a garbage collector?

So are we stuck with a garbage collector?

No! We can use linear types!

Every variable must be used **exactly once**

```
Linear arrow: —o
Normal arrow: →
const :: a -o b -o c
const a b = a -- error
append :: [a] -o [a] -o [a]
append [] ys = ys
append (x:xs) ys = x : append xs ys -- good
```

- Some programs no longer compile
- No need to copy the data structure, instead mutate!

- Returning x unmodified.
 - + f x = x

- Returning x unmodified.
 - + f x = x
- Passing x to a linear function g and using the result exactly once in the same fashion.
 - f x = g x

- Returning x unmodified.
 - + f x = x
- Passing x to a linear function g and using the result exactly once in the same fashion.
 - f x = g x
- Pattern-matching on x and using each argument exactly once in the same fashion.
 - ▶ f x = case x of
 Pair a b -> a + b

- Returning x unmodified.
 - + f x = x
- Passing x to a linear function g and using the result exactly once in the same fashion.
 - + f x = g x
- Pattern-matching on x and using each argument exactly once in the same fashion.
 - ▶ f x = case x of
 Pair a b -> a + b
- Calling it as a function and using the result exactly once in the same fashion.
 - f x = x + 1 g = let k = f 0 in f k

System-level Functional Language (SLFL)

The point of our thesis will be to create a compiler for a SLFL

We want to add several higher level concepts such as:

- Closures
 - Allows lambas to capture variables from their environment

```
fun :: Int -> (Int -> Int)
fun x = y -> x + y -- x is captured here
```

- Records
 - Data types with named fields. Pretty simple
- Recursive & Contiguous Data Types
 - Trees, linked lists etc and Vectors/Arrays
- Laziness

How will the language be evaluated?

Objectively evaluating languages is hard, but some things can be done!

- Performance:
 - Programs will be written in another system-level language (C etc) and SLFL Results will be compared based on execution time and memory usage
- Binary size:
 Small binaries are good for portability
 Our thesis will not focus a lot on this, but it is an interesting metric nonetheless

Why us?

Why us?

- All FP courses
- All language development courses
- Made a functional programming language for our bachelor thesis
- Good teamwork
- Motivated

Risk assessment and proposed mitigation

- Too complex
- Impossible task

Risk assessment and proposed mitigation

- Too complex
